

Fig. 4

(34) Stable, single-phased solutions of water-in-oil microemulsions which contain microorganisms and/or parts thereof are described. They are obtained by adding to crude oil and/or at least one product of the refining of same an aqueous concentrated solution of microorganisms and/or parts thereof, in such a way that said aqueous solution is solubilized in crude oil or the refined product; and that the blend thus obtained has the form of a stable, single-phased solution.

(35) Stable, single-phased solutions of water-in-oil microemulsions derived from crude oil and allied products and which contain microorganisms and/or parts thereof.

which form spheroidal aggregates, in which the polar heads of the molecules of the capillary-active agent form a polar core. In such a core it is possible to solubilize water (pp. 3). Whenever the water content in a ternary system is comparatively high, water-in-oil microemulsion is spoken of, and reversible micelles are no more mentioned. However, in the common practice, the difference between the two fields has not been made quite clear.

The invention is illustrated by the accompanying drawings, wherein:

Fig. 1 is a diagrammatical showing of (a) normal aqueous micelles, and (b) reversible micelles as

Fig. 2 is a diagrammatical showing of the introduction of a core in the "water core" (aqueous core) of reversible micelles

Fig. 3 depicts the difference between a bacterial-containing single-phase system (a) and the corresponding single-phase system (b), and

Fig. 4 shows the stability of core solubilized in crude oil by means of asphaltenes (65 mM) and water (1M) as explained in the examples.

The difference between the normal aqueous micelles (a) and the reversible micelles (b) is shown in Fig. 1 of the accompanying drawings.

The water core in the reversible micelles, or in the water-in-oil microemulsions, is of outstanding importance, because it becomes possible to dissolve biopolymers in such water droplets in a secondary solubilization process. Thermodynamically stable solutions are obtained, which are clear and in which the enzymes retain their activity.

A graphic representation of the solubilization process referred to above is presented in Fig. 2.

In recent years it has also been made known that E. coli bacteria and other small bacteria could be solubilized in the solvent isopropyl palmitate (IPP) by the agency of the capillary-active agent Tween (reg. Trade mark) (ref. 1).

Within a solution of the capillary-active agent Tween 85 (Reg. Trade Mark) in IPP, reversible micelles are formed at the outset, whereas a small volume of a microorganism-containing aqueous solution was added. Whenever the concentration of the bacteria and/or the volume of water is not too high, the result of this procedure is a clear solution, in which viable and active bacteria can be detected.

The same group of searchers has subsequently solubilized also mitochondria in the same system (ref. 12).

Later, it has been announced by a Group in Mexico (ref. 13) that it is possible to solubilize spores, bacteria and yeast cells in toluene, and this with phospholipids as the capillary-active agents, however with a restricted viability of the cells.

This invention relates to stable, single-phase solutions of microorganism-containing water-in-oil microemulsions, which are obtained from crude oil or crude-oil derivatives.

In order to remove sulphur-containing products from crude oil, naphtha and derivatives, attempts have been made long since to find microbiological procedures. As microorganisms, as can be seen, for example in a comprehensive paper published in 1978 by Malik (ref. 1) at the end of the present specification), and themselves Desulfotribiotic desulfuricans, *Arthrobacter* Sp., *Pseudomonas* Sp., *Rhizobium* sp., *Acinetobacter* sp., *Later*, also *Pseudomonas alcaligenes*, *Alcaligenes denitrificans*, *Scitobolus acidocalcalarius*, *Thiobacillus ferrooxidans* have been proposed (ref. 2-6).

The problem of removal of sulphur from crude oil is connected with that of removal of sulphur from coal, and the above cited literature references (1-6) and in other references (7-8) this subject matter is thoroughly discussed. A comprehensive article by Andrews and Maczuga discusses this problem.

Inasmuch as nearly all microorganisms, and thus also the ones referred to above, can survive in crude oil poorly, the rules to work in a two-phase system, wherein the microorganisms are introduced into an aqueous phase which is immiscible with crude oil. The reaction takes place at the interface, so that it is necessary to renew such contact surfaces continuously with a vigorous stirring.

A new interesting paper on the argument of the biphasic systems has appeared recently (ref. 6). In such case the authors use in the organic phase a capillary-active agent (Tween 80, Reg. Trade Mark), which possesses the capability of building reversible micelles within organic solvents. They achieve thereby a significant success in removing sulphur from coal. The authors, however, warn that enzymatic preparations are much more efficient than the corresponding microorganisms as such (ref. 6).

It would be an asset, of course, for the microbiological demulsification, should one be enabled to work within a single homogeneous phase, rather than within a biphasic system. This means, however, to find conditions under which the microorganisms, scattered throughout the crude oil homogeneously, are present in solution.

The solubilization of water-soluble proteins and other biopolymers in organic solvents by the agency of reversible micelles or water-in-oil microemulsions, is known a few years since (ref. 9, 10).

Contrary to the normal aqueous micelles, the reversible micelles are formed in apolar solvents. To this end capillary-active agents are employed.

ganisms (bacteria and eukariotic cells), must be still closer investigated.

The solutions prepared according to this invention are stable, transparent and homogeneous single-phase systems.

It is important to emphasize that, in the solutions made according to this invention, contrary to the Kwang-Il Lee and Teh-Fu Yen system (ref.6), no biphasic system is formed. According to Kwang-Il Lee et al., the bacteria are not solubilized in the micellar phase, but, rather, they are present in the aqueous phase (see Fig.3a). A diagrammatical showing of the difference between the two systems is reproduced in Fig.3.

It is likewise important to add that, under the conditions selected by Kwang-Il and Teh-Fu, the bacteria cannot be conveyed in the supernatant phase, that is to say that in the a) system it is not possible to directly obtain a situation such as that corresponding to what is represented at b).

For these reasons the two procedures are substantially and radically different from one another.

According to the present invention, different types of bacteria are solubilized in crude-oil products by the agency of different capillary-active agents, eg. Tween 85 and Asacrin, in the absence of capillary-active agents and/or water, no solubilization occurs; one obtains a suspension of cells which segregate comparatively rapidly.

It had been established that, in the case of certain defined types of crude oil, which, as a rule, occur in the form of a black suspension and usually contain many compounds, capillary-active agents should not be introduced, absolutely. Stated another way, it is permissible to add directly to the oil, without any special pre-treatment, an aqueous microorganism-containing solution. Without being bound to any special theory, it is surmised that this circumstance is presumably to be attributed to the fact that crude oil already contains molecules which are similar to those of the capillary-active agents.

This observation is of course very important from the biotechnological standpoint, because, on its basis, the potential process of the microbiological decomposition of crude oil would become much cheaper and simpler.

Water, however, must be added also in such a case.

In order that a single phase might be obtained, it is important that the volume of the added aqueous solution should not overtake the limits of the thermodynamic stability of the microemulsion system, or, stated alternatively, if too much water is added, a biphasic system is obtained.

It has been quite surprisingly ascertained that many microorganisms, which are contained in the solutions prepared according to this invention, are

All the studies referred to above on bacteria in a homogeneous phase are restricted to few conventional organic solvents; crude oil and other naturally occurring oils have not been mentioned heretofore.

The objective of the present invention is thus to improve the state of the art referred to above, and to provide stable, single-phased solutions of water-in-oil microemulsions which contain microorganisms and/or parts of microorganisms.

The invention is defined by the characteristics reported in the independent claims. Preferred embodiments of this invention are defined in the dependent claims.

The main characteristic of the present invention consists in that conditions have been found in which bacteria, yeast cells and other microorganisms can be solubilized in crude oil, that is to say a way that they do not decay for longer times, independent of the selected system. The microorganisms are introduced in the form of an aqueous solution, eg. with a nebulizer, the technique of the internal spray, and the water is completely solubilized by the crude oil.

The situation in the case of the solubilization of proteins can be diagrammatically represented, see Fig.2. It is readily surmised that the cells remain in solution since it would be forecast that they, due to their size, should show a tendency towards sedimentation from the solution already after a short time, due to the gravity pull, and towards aggregation. Without going bound to any special theory, it is surmised that the stabilization of the microorganisms in solution is to be construed as a consequence of the formation of a microemulsion; the microorganisms, particularly the bacteria, which are present in the water droplets, are a component part of the water-in-oil microemulsion system, and clearly remain blocked in the organic solution as guest-compounds in the stable aggregates which are geometrically closed by the capillary-active agent molecules.

Presumably, the bacteria are protected by a few water layers and by a layer of capillary-active agent molecules, whereby the solubility in an organic medium is made possible.

Fig.3 renders a graphic representation, which, however, is to be construed merely diagrammatic, inasmuch as accurate experimental data on the structure of the micellar aggregates of bacteria are not yet available.

The special difference in density between microorganisms and solvents, and the advantageous value of the increment of the count index, dn/dc, contribute to a degree towards the optical clarity and the reduction of the dispersion of light.

As outlined above, all the factors contributing towards the formation of clear solutions of microor-

present in crude oil are in a microemulsion, which acterized in that the microorganisms which are literature, the process proposed herein is char-

Contrary to other processes provided in the capillary-active agents. is possible to work also without any addition of obtained by refining, where in the case of raw oil it which are solubilized in crude oil or in a product agents are preferably used (eg Tween or lipids), not precipitate during a long time. Capillary-active single liquid phase, for which microorganisms do aqueous phase in mineral oil, so as to obtain a dissolve microorganisms, preferably bacteria, in an A process is proposed, which makes it possible to can be summarized as follows:

The important features of the present invention can be summarized as follows:

Typical results are shown in Fig. 4. It can be seen that the different bacteria and cells differ from each other as to stability, but the stability in many cases is designated as very good. Details can be found in the description of the Figure or the exam-

To this end, the activity of the microorganisms is tested on agar plates; the concentration of the viable cells is determined by staining with a crude aqueous NaOH, a measurable number of cells (about 100 per each Petri-dish), 100% viability corresponds to the cell concentration at the start ( $t=0$ ).

The objective of this work consists in investigating the viability of the microorganisms in the systems obtained in the above indicated way.

Second stage: Determination of the viability of the microorganisms in crude oil products

With the procedure as outlined above, the following microorganisms were investigated:

Baker's yeast, *Pseudomonas* spp., *Bifidobacter*, *Thiobacter* sulfidans, *Bacillus* sp., *Arthrospira* spp. HAT, the details of which are reported in the examples.

All of these systems remain stable, that is, no significant precipitation of the cells was observed during a few weeks.

First stage: Preparation of a single-phase system

Typically, 500 mg of Tween 85 or 250 mg of Ascorbin were solubilized in 5 ml of a crude oil product at room temperature and with vigorous stirring (10% or 5% weight/volume, respectively). The aqueous suspension of the cells was adjusted with an appropriate nutrient medium for the microorganism concerned, to a concentration (typical) of  $10^6$  cells/ml. With a microspray a small volume of this solution (about 2% v/v) of the organic capillary-active agent solution was added, and vigorously shaken (about 1600 rpm). Shaking was discontinued after a few minutes. With larger cells, a short ultra-sound treatment may shorten the shaking time.

The solubilization of cells in crude oil without capillary-active agent added follows in the above mentioned way. By varying the water concentration, it is possible to determine the limits for building a homogeneous phase.

It has been ascertained that in motor oil (Tellus 33, Shell) it is possible to solubilize up to about 1% of water (v/v); in the case of crude oil, it is possible to add up to the double volume of water, but it is to be mentioned that the opacity of the product hardly permits that a clear boundary may be detected.

In this manner the micellar solutions of motor oil and mineral oil contain from about  $10^7$  to  $10^8$  cells/ml (counted relative to the total volume).

It is possible to go beyond these limits, while still having a single-phase system, if a greater concentration of capillary-active agent is employed, eg. in the case of Asolectin, one can solubilize twice more water by coupling the concentration of the capillary-active agent and, thereby, add more cells correspondingly.

In this connection, attention is also directed to the fact that, above a certain cell concentration, the

in a position to carry out microbiological reactions even in an environment unfavourable to life, such as crude oil, does not affect.

Thereby the basic principles are provided for carrying out microbiological processes in crude oil and in the products of its refining.

In a first stage of the programme, experiments have been conducted, the aim of which was to determine that bacterial cells can be directly solubilized in mineral oil or in naphtha, and that such single-phase systems are stable, that is, that they do not bring about any phase splitting, even when the system is not shaken. In a second stage, the viability of the microorganisms in such systems was investigated.

Both these stages of the programme are described hereinafter.

First stage: Preparation of a single-phase system

Typically, 500 mg of Tween 85 or 250 mg of Ascorbin were solubilized in 5 ml of a crude oil product at room temperature and with vigorous stirring (10% or 5% weight/volume, respectively). The aqueous suspension of the cells was adjusted with an appropriate nutrient medium for the microorganism concerned, to a concentration (typical) of  $10^6$  cells/ml. With a microspray a small volume of this solution (about 2% v/v) of the organic capillary-active agent solution was added, and vigorously shaken (about 1600 rpm). Shaking was discontinued after a few minutes. With larger cells, a short ultra-sound treatment may shorten the shaking time.

The solubilization of cells in crude oil without capillary-active agent added follows in the above mentioned way. By varying the water concentration, it is possible to determine the limits for building a homogeneous phase.

It has been ascertained that in motor oil (Tellus 33, Shell) it is possible to solubilize up to about 1% of water (v/v); in the case of crude oil, it is possible to add up to the double volume of water, but it is to be mentioned that the opacity of the product hardly permits that a clear boundary may be detected.

In this manner the micellar solutions of motor oil and mineral oil contain from about  $10^7$  to  $10^8$  cells/ml (counted relative to the total volume).

It is possible to go beyond these limits, while still having a single-phase system, if a greater concentration of capillary-active agent is employed, eg. in the case of Asolectin, one can solubilize twice more water by coupling the concentration of the capillary-active agent and, thereby, add more cells correspondingly.

In this connection, attention is also directed to the fact that, above a certain cell concentration, the

The same procedure as in Example 1 is followed, with yeast in a solution of 250 mg Tween 85 in 2.5 ml of isopropylalmitate, which is mixed with 2.5 ml of Tellus 33 motor oil (She1).

#### EXAMPLE 3:

From a solution of 30 mg/ml of Pseudomonas sp. in a nutrient medium, 100 microliters are added to a solution of Asiolectin-crude oil. (Procedure as in Example 3).

#### EXAMPLE 7:

The same volume of a spore solution of the *Bacillus subtilis* is solubilized as in Example 6 or Example 1 in Asiolectin crude oil.

#### EXAMPLES 8-10:

As described in Example 6, *Arthrobacter* spp. (grown for 2 days from butanol), *Sulfolobus* Acetolactatus and *Thiobacillus* sulfoxidans can likewise be introduced.

brings about an efficient contact with the solvent, no stirring is potentially required to secure a reaction of the microorganisms with the compounds which are present in the crude oil.

The invention makes it possible to treat microbologically a crude oil preparation under a stationary condition.

Among others, those microorganisms are solubilized in crude oil, which are capable of demolishing sulphur-containing products. Possible chemical demolition processes and the appropriate reactions are the target of further research work.

It is moreover shown that the viability of the microorganisms can be extended for weeks, and that during such a time, no significant precipitation of the cells can be observed.

### EXAMPLES

#### EXAMPLE 1:

100 mg of yeast are suspended in 1 ml of nutrient medium (YPD, consisting of 1% yeast extract, 2% bacto-peptone, 2% glucose in water). 100 microliters of the suspension are sprayed in 5 ml of crude oil and stirred at 1600 rpm for about half an hour, until obtaining a homogeneous phase.

#### EXAMPLE 2:

The yeast is processed as outlined above and the same volume is transferred into 5 ml of a solution of crude oil with 10% Tween 85, and stirred to homogeneity just as in Example 1.

#### EXAMPLE 3:

The same procedure as in Example 1 is followed, with yeast in a solution of 250 mg of Asiolectin in 5 ml of crude oil.

#### EXAMPLE 4:

The same procedure as in Example 1 is adopted, with yeast in a solution of 250 mg of Asiolectin in 5 ml of Tellus 33 motor oil (She1).

## Claims

1. Stable, single-phased solutions of water-in-oil and/or at least one of the product of its refining and/or parts thereof, obtained by adding to crude oil and/or at least one of the product of its refining an aqueous, concentrated solution of microorganism and/or parts of microorganisms in such a way that the above named aqueous solution becomes solubilized in said crude oil and/or the product of its refining, the thus prepared blend being in the form of a stable, single-phased solution.
2. Solutions according to claim 1, characterized in that at least one capillary-active substance is dissolved in crude oil and/or a product of its refining, particularly in proportion of from 0.1% to 30% by weight, preferably from 0.5% to 15% by weight, reckoned relative to the weight of the crude oil and/or refining product concerned.
3. Solutions according to claim 1 or 2, characterized in that the capillary-active substance is selected from the group consisting of anionic, cationic, neutral and zwitterionic capillary-active substances, particularly Bril, Tween, Span, lipids, such as lecithin, Asolfatin, AOT and other surfactants, ammonium salts and oxethylene compounds.
4. Solutions according to one of claims 1 to 3, characterized in that the microorganisms are bacteria, particularly those of the group of the cacteria which possess a reducing or an oxidizing action towards sulphur-containing products, such as Thiobacillus ferrooxidans, or Sulfolobus acidocaldarius, Pseudomonas alkalicus, Pseudomonas jactans and Pseudomonas abikensis and other Pseudomonas, and also E. coli, Sulfolobus acidocaldarius, Alkaligenes denitrificans, Desulfotomaculum, Arthrobacter species or the like of the family of the photosynthetic bacteria, such as cyanobacteria, or animal or vegetable cells, particularly yeast cells of the different strains, which possess a demolishing activity or a transposition capability towards aromatic compounds, such as Saccharomyces cerevisiae, Candida utilis.
5. Solutions according to one of the claims 1 to 4, characterized in that the parts of microorganisms are selected from spores and heterocysts or from organelles of the microorganism cell, such as mitochondria, microsomes, lysosomes.
6. Solutions according to one of the claims 1 to 5, characterized in that at least one co-capillary-active agent, which is preferably selected from fatty acids, alcohols and fragrance-containing compounds, is added to the capillary-active substance, and particularly in an amount of from 0.01% to 1000%, preferably from 0.1% to 100% by weight reckoned relative to the weight of the capillary-active substance concerned.
7. Solutions according to one of claims 1 to 6, characterized in that in 100 parts by volume of crude oil and/or a product of its refining, from 0.001 to 100 parts by volume of said aqueous solution are present.
8. Solutions according to one of claims 1 to 7, characterized in that the aqueous, concentrated solution additionally contains nutrients and salts for the microorganisms.
9. Solutions according to one of claims 1 to 8, characterized in that the selected product of refining of the various crude oils derives from the group consisting of mineral oil, motor oils, naphtha, kerosene, fuel oil, in the different obtainable qualities, e.g. light or heavy.
10. Solutions according to claims 1 to 9, characterized in that the crude oil or the product of its refining thereof is blended with at least an organic solvent, preferably aromatic hydrocarbons, e.g. benzene, toluene, xylene, aliphatic hydrocarbons, e.g. pentane, octane, dodecane, fatty acid esters, alcohols, halogen-substituted, particularly fluorinated and perfluorinated compounds, and/or with at least one vegetable oil, e.g. from soybean seeds, sunflower seeds, coza seeds and olives, and preferably in an amount of from 1 to 1000% by volume reckoned relative to the crude oil or product of its refining concerned.
11. Solutions according to one of claims 1 to 10, characterized in that the capillary-active agents and/or the co-capillary-active agents and/or further specially added compounds have the property of disorganizing the cells of microorganisms so as to set free the enzymes and/or proteins contained therein.
12. Solutions according to one of claims 1 to 11, characterized in that they further contain compounds which are capable of exalting the viscosity of the whole system to its maximum to the form of gels or of extremely viscous masses, so that a possible precipitation of microorganisms is still further braked, e.g. glycerol, viscous oils, waxes, polymers.
13. Solutions according to one of claims 1 to 12, characterized in that they additionally contain an excess of microorganisms in the form of a suspension.
14. Solutions according to one of claims 1 to 13, characterized in that they additionally contain compounds.

pounds which form chelates or complexes with metals or metal ions, particularly with Vanadium, Nickel, Iron and Arsenic.

15. A process for preparing stable, single-phased solutions of water-in-oil microemulsions which con-

tain microorganisms and/or parts of microorgan-isms, characterized in that an aqueous, concen-tered solution of microorganisms and/or parts of microorganisms is added to crude oil and/or to at least one of the products of refining of crude oil, in such a way that said aqueous solution become

solubilized in said crude oil and/or product of its refining and that the so prepared blend has the form of a stable, single-phased solution.

16. Process according to claim 15, characterized in that solutions according to one of claims 2 to 14

are prepared  
17. Use of the solutions according to one of claims 1 to 14 for removing sulphur and/or reducing the sulphur content in coal or crude oil or in one of the products of refining of the latter, particularly from mineral oil, motor oil, naphtha, kerosene, fuel oil or in the different obtainable densities, eg light or heavy.
